## Homework for Section 4.4: 50 points

In Problems 27 - 36 solve the given initial-value problem.

### Problem 4.4.30

Given: $y'' + 4y' + 4y = (3 + x) e^{-2x}$;   $y(0) = 2, \ y'(0) = 5$
Find:  $y(x)$

**SOLUTION:** When we are solving for our general solution, we must first solve for our complementary solution, using auxiliary equations, and solve for our paricular solution, using the method of undetermined coefficients. Then we can use our IVP to solve for our constants.

Solving auxiliary equation for $y_c(x)$.

$$y'' + 4y' + 4y = 0$$
$$m^2 + 4m + 4 = 0$$
$$m = (m + 2)^2, \ m = -2, -2$$
$$\Longrightarrow \boxed{y_c(x) = C_1 e^{-2x} + C_2 x e^{-2x}}$$

Method of undetermined coefficients for $y_p(x)$. Notice how there are multiple repeated roots for $e^{-2x}$.

$$\text{Assume: } y_p(x) = x^2(Ax + B)e^{-2x}$$
$$y_p(x) = (Ax^3 + Bx^2)e^{-2x}$$
$$y_p'(x) = (3Ax^2 + 2Bx - 2Ax^3 - 2Bx^2)e^{-2x}$$
$$y_p'(x) = (-2Ax^3 + 3Ax^2 - 2Bx^2 + 2Bx)e^{-2x}$$
$$y_p''(x) = (-6Ax^2 + 6Ax - 4Bx + 2B + 4Ax^3 - 6Ax^2 + 4Bx^2 - 4Bx)e^{-2x}$$
$$y_p''(x) = (4Ax^3 - 12Ax^2 + 4Bx^2 + 6Ax - 8Bx + 2B)e^{-2x}$$

Substitute $y_p(x)$ and solve for constants.

$$y_p(x)'' + 4y_p(x)' + 4y_p(x) = (3 + x)\,e^{-2x}$$
$$(4Ax^3 - 12Ax^2 + 4Bx^2 + 6Ax - 8Bx + 2B)e^{-2x} + 4(-2Ax^3 + 3Ax^2 - 2Bx^2 + 2Bx)e^{-2x} + 4(Ax^3 + Bx^2)e^{-2x} = (3 + x)\,e^{-2x}$$
$$(4Ax^3 - 12Ax^2 + 4Bx^2 + 6Ax - 8Bx + 2B) + (-8Ax^3 + 12Ax^2 - 8Bx^2 + 8Bx) + (4Ax^3 + 4Bx^2) = 3 + x$$
$$6Ax + 2B = 3 + x$$
$$\implies \begin{cases} 6Ax = x \\ 2B = 3 \end{cases}$$
$$A = \frac{1}{6}, \ B = \frac{3}{2}$$
$$\implies \boxed{y_p(x) = \left(\frac{1}{6}x^3 + \frac{3}{2}x^2\right)e^{-2x}}$$

Combine to create $y_g(x)$.

$$y_g(x) = y_c(x) + y_p(x)$$
$$\implies \boxed{y_g(x) = C_1e^{-2x} + C_2xe^{-2x} + \left(\frac{1}{6}x^3 + \frac{3}{2}x^2\right)e^{-2x}}$$

Now we have to solve the IVP and obtain our constants.

$$y(0) = 2, \ y'(0) = 5$$
$$y_g(x) = C_1e^{-2x} + C_2xe^{-2x} + \left(\frac{1}{6}x^3 + \frac{3}{2}x^2\right)e^{-2x}$$
$$y_g'(x) = -2C_1e^{-2x} + C_2e^{-2x} - 2C_2xe^{-2x} + \left(\frac{1}{2}x^2 + 3x\right)e^{-2x} - 2\left(\frac{1}{6}x^3 + \frac{3}{2}x^2\right)e^{-2x}$$
$$y_g'(x) = -2C_1e^{-2x} + C_2e^{-2x} - 2C_2xe^{-2x} + \left(\frac{1}{2}x^2 + 3x\right)e^{-2x} + \left(-\frac{1}{3}x^3 - 3x^2\right)e^{-2x}$$

Plugging in.

$$y(0) = 2$$
$$y_g(0) = C_1e^{-2(0)} + C_2(0)e^{-(0)} + \left(\frac{1}{6}(0)^3 + 3(0)^2\right)e^{-2(0)} = 2$$
$$y_g(0) = C_1 = 2$$
$$y'(0) = 5$$
$$y_g'(0) = -2C_1e^{-2(0)} + C_2e^{-2(0)} - 2C_2(0)e^{-2(0)} + \left(\frac{1}{2}(0)^2 + 3(0)\right)e^{-2(0)} + \left(-\frac{1}{3}(0)^3 - 3(0)^2\right)e^{-2(0)} = 5$$
$$y_g'(0) = -2C_1 + C_2 = 5$$
$$y_g'(0) = -2(2) + C_2 = 5$$
$$y_g'(0) = C_2 = 9$$

2

Combine to create $y(x)$.

$$C_1 = 2, \ C_2 = 9$$

$$y_g(x) = C_1 e^{-2x} + C_2 x e^{-2x} + \left(\frac{1}{6}x^3 + \frac{3}{2}x^2\right)e^{-2x}$$

$$\implies \boxed{y_g(x) = 2e^{-2x} + 9xe^{-2x} + \left(\frac{1}{6}x^3 + \frac{3}{2}x^2\right)e^{-2x}}$$

## Problem 4.4.34

Given: $\dfrac{d^2x}{dt^2} + \omega^2 x = F_0 \cos(\gamma t); \quad x(0) = 0, \ x'(0) = 0$

Find: $x(t)$

**SOLUTION:** When we are solving for our general solution, we must first solve for our complementary solution, using auxiliary equations, and solve for our paricular solution, using the method of undetermined coefficients. Then we can use our IVP to solve for our constants.

Solving auxiliary equation for $x_c(t)$.

$$\frac{d^2x}{dt^2} + \omega^2 x = F_0 \cos \gamma t$$
$$m^2 + \omega^2 = 0$$
$$m = \pm i\omega$$
$$\implies \boxed{x_c(t) = C_1 \cos(\omega t) + C_2 \sin(\omega t)}$$

Method of undetermined coefficients for $x_p(t)$.

$$\text{Assume: } x_p(t) = A\cos(\gamma t) + B\sin(\gamma t)$$
$$x_p'(t) = -\gamma A \sin(\gamma t) + \gamma B \cos(\gamma t)$$
$$x_p''(t) = -\gamma^2 A \cos(\gamma t) - \gamma^2 B \sin(\gamma t)$$

Substitute $x_p(t)$ and solve for constants.

$$\frac{d^2 x_p(t)}{dt^2} + \omega^2 x_p(t) = F_0 \cos(\gamma t)$$
$$\left(-\gamma^2 A \cos(\gamma t) - \gamma^2 B \sin(\gamma t)\right) + \omega^2 \left(A \cos(\gamma t) + B \sin(\gamma t)\right) = F_0 \cos(\gamma t)$$
$$\left(-\gamma^2 A \cos(\gamma t) - \gamma^2 B \sin(\gamma t)\right) + \left(\omega^2 A \cos(\gamma t) + \omega^2 B \sin(\gamma t)\right) = F_0 \cos(\gamma t)$$
$$A(\omega^2 - \gamma^2)\cos(\gamma t) + B(\omega^2 - \gamma^2)\sin(\gamma t) = F_0 \cos(\gamma t)$$
$$\implies \begin{cases} A(\omega^2 - \gamma^2)\cos(\gamma t) = F_0 \cos(\gamma t) \\ B(\omega^2 - \gamma^2)\sin(\gamma t) = 0 \end{cases}$$
$$A = \frac{F_0}{\omega^2 - \gamma^2}, \ B = 0$$
$$\implies \boxed{x_p(t) = \frac{F_0}{\omega^2 - \gamma^2}\cos(\gamma t)}$$

Combine to create $x_g(t)$.

$$x_g(t) = x_c(t) + x_p(t)$$

$$\implies \boxed{x_g(t) = C_1 \cos(\omega t) + C_2 \sin(\omega t) + \frac{F_0}{\omega^2 - \gamma^2} \cos(\gamma t)}$$

Now we have to solve the IVP and obtain our constants.

$$x(0) = 0, \ x'(0) = 0$$

$$x_g(t) = C_1 \cos(\omega t) + C_2 \sin(\omega t) + \frac{F_0}{\omega^2 - \gamma^2} \cos(\gamma t)$$

$$x_g'(t) = -\omega C_1 \sin(\omega t) + \omega C_2 \cos(\omega t) - \frac{F_0 \gamma}{\omega^2 - \gamma^2} \sin(\gamma t)$$

Plugging in.

$$x_g(0) = C_1 + \frac{F_0}{\omega^2 - \gamma^2} = 0$$

$$x_g(0) = C_1 = -\frac{F_0}{\omega^2 - \gamma^2}$$

$$x_g'(0) = -\omega C_1 \sin(\omega(0)) + \omega C_2 \cos(\omega(0)) - \frac{F_0 \gamma}{\omega^2 - \gamma^2} \sin(\gamma(0))$$

$$x_g'(0) = \omega C_2 = 0 \qquad\qquad\qquad\qquad x_g'(0) = C_2 = 0$$

Combine to create $x(t)$.

$$C_1 = -\frac{F_0}{\omega^2 - \gamma^2}, \ C_2 = 0$$

$$x_g(t) = C_1 \cos(\omega t) + C_2 \sin(\omega t) + \frac{F_0}{\omega^2 - \gamma^2} \cos(\gamma t)$$

$$x(t) = -\frac{F_0}{\omega^2 - \gamma^2} \cos(\omega t) + \frac{F_0}{\omega^2 - \gamma^2} \cos(\gamma t)$$

$$\implies \boxed{x(t) = \frac{F_0}{\omega^2 - \gamma^2} (\cos(\gamma t) - \cos(\omega t))}$$

## Problem 4.4.42

In Problems 41 and **42** solve the given initial-value problem in which the input function $g(x)$ is discontinuous. [*Hint*: Solve each problem on two intervals, and then find a solution so that $y$ and $y'$ are continuous at $x = \pi/2$ (Problem 41) and $\boldsymbol{x = \pi}$ (**Problem 42**)]

Given: $y'' + 4y = g(x), \ y(0) = 1, \ y'(0) = 2$, where

$$g(x) = \begin{cases} 20 & 0 \le x \le \pi \\ 0 & x \ge \pi \end{cases}$$

Find: $y(x)$

**SOLUTION:** This problem is unique as it is two nonhomogenous problems in one. We will solve both general solutions normally as the past two. We will be able to find our first set of constants for the range of $\le x \le \pi$ by just normally plugging in. For the range of $x \ge \pi$, we will have to make it satisfy continuity and smoothness continuity. In other words, $y_1(\pi) = y_2(\pi)$ for continuity and $y_1'(\pi) = y_2'(\pi)$ for smoothness.

4

Solving for $y_{1c}(x)$ for range of $0 \leq x \leq \pi$.

$$y'' + 4y = 20$$
$$m^2 + 4 = 0$$
$$m = \pm 2i$$
$$\Longrightarrow \boxed{y_{1c}(x) = C_1 \cos(2x) + C_2 \sin(2x)}$$

Solving for $y_{1p}(x)$ for range of $0 \leq x \leq \pi$.

$$\text{Assume: } y_{1p}(x) = A$$
$$y_{1p}^{(n)}(x) = 0, \quad n \in \mathbb{Z}^+, \ n \geq 1$$
$$y_{1p}'' + 4y_{1p} = 20$$
$$4A = 20$$
$$A = 5$$
$$\Longrightarrow y_{1p}(x) = 5$$

Solving for $y_{1g}(x)$ and $y_{1g}'(x)$.

$$y_{1g}(x) = y_{1c}(x) + y_{1p}(x)$$
$$y_{1g}(x) = C_1 \cos(2x) + C_2 \sin(2x) + 5$$
$$y_{1g}'(x) = -2C_1 \sin(2x) + 2C_2 \cos(2x)$$

Plugging in for constants.

$$y(0) = 1, \ y'(0) = 2$$
$$y_{1g}(0) = C_1 \cos(2(0)) + C_2 \sin(2(0)) + 5 = 1$$
$$y_{1g}(0) = C_1 + 5 = 1$$
$$y_{1g}(0) = C_1 = -4$$
$$y_{1g}'(0) = -2C_1 \sin(2(0)) + 2C_2 \cos(2(0)) = 2$$
$$y_{1g}'(0) = 2C_2 = 2$$
$$y_{1g}'(0) = C_2 = 1$$

Combine for $y_{1g}(x)$ for range of $0 \leq x \leq \pi$.

$$C_1 = -4, \quad C_2 = 1$$
$$y_{1g}(x) = C_1 \cos(2x) + C_2 \sin(2x) + 5$$
$$\Longrightarrow \boxed{y_1(x) = -4\cos(2x) + \sin(2x) + 5}$$

Now the same thing for $y_2(x)$ for the range of $x \geq \pi$. We should recognize this is just the homogenous, complementary part from $y_1(x)$ so we can skip and state the following. There is no particular solution as it is homogenous.

$$y'' + 4y = 0$$
$$\Longrightarrow y_{2g}(x) = y_{1c}(x)$$
$$\boxed{y_{2g}(x) = C_1 \cos(2x) + C_2 \sin(2x)}$$

Now have to have to satisfy continuity and smoothness continuity for our constants.

$$y_1(0) = y_2(0)$$
$$y_{1g}(x) = -4\cos(2x) + \sin(2x) + 5$$
$$y_{1g}(0) = 1$$
$$y_{2g}(x) = C_1\cos(2x) + C_2\sin(2x)$$
$$y_{2g}(0) = C_1$$
$$y_1(0) = y_2(0)$$
$$C_1 = 1$$

$$y_1'(0) = y_2'(0)$$
$$y_1'(x) = 8\sin(2x) + 2\cos(2x)$$
$$y_1'(0) = 2$$
$$y_{2g}'(x) = -2C_1\sin(2x) + 2C_2\cos(2x)$$
$$y_{2g}'(0) = 2C_2$$
$$y_1'(0) = y_2'(0)$$
$$2 = 2C_2$$
$$C_2 = 1$$

$$y_{2g}(x) = C_1\cos(2x) + C_2\sin(2x)$$
$$\implies \boxed{y_2(x) = \cos(2x) + \sin(2x)}$$

Combining everything.

$$\boxed{y(x) = \begin{cases} -4\cos(2x) + \sin(2x) + 5 & 0 \le x \le \pi \\ \cos(2x) + \sin(2x) & x \ge \pi \end{cases}}$$

# Homework for Section 4.6: 50 points

In Problems 1 - 20 solve each differential equation by variation of parameters.

For second order, we will assume our particular solution comes in this form.

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

After a process, we will arrive with these pairs of equations.

$$\text{Assume: } u_1'(x)y_1(x) + u_2'(x)y_2(x) = 0$$
$$\implies u_1'(x)y_1'(x) + u_2'(x)y_2(x) = f(x)$$

By Cramer's Rule.

$$u_1'(x) = \frac{W_1}{W} \tag{2}$$

$$u_2'(x) = \frac{W_2}{W} \tag{3}$$

# Problem 4.6.4

Given: $y'' + y = \sec\theta\tan\theta$
Find: $y_g(x)$

**SOLUTION:** We simply use auxiliary equations for our complimentary equation and Cramer's rule to find our $u_1'$ and $u_2'$ to find our particular solution $y_p(x)$.

Solving for $y_c(x)$.

$$y'' + y = \sec\theta\tan\theta$$
$$m^2 + 1 = 0$$
$$m = \pm i$$
$$\Longrightarrow \boxed{y_c(x) = C_1\cos(\theta) + C_2\sin(\theta)}$$

Solving for determinants $W$, $W_1$, $W_2$.

$$y_p(\theta) = u_1 y_1 + u_2 y_2$$
$$y_1(\theta) = \cos(\theta), \;\; y_2(\theta) = \sin(\theta), \;\; f(\theta) = \sec\theta\tan\theta$$
$$W = \begin{vmatrix} \cos(\theta) & \sin(\theta) \\ -\sin(\theta) & \cos(\theta) \end{vmatrix} = 1$$
$$W_1 = \begin{vmatrix} 0 & \sin(\theta) \\ \sec\theta\tan\theta & \cos(\theta) \end{vmatrix} = -\tan^2(\theta)$$
$$W_2 = \begin{vmatrix} \cos(\theta) & 0 \\ -\sin(x) & \sec\theta\tan\theta \end{vmatrix} = \tan(\theta)$$

Solving for $u_1(\theta)$ and $u_2(\theta)$.

$$u_1(\theta) = \int \frac{W_1}{W}\,d\theta$$
$$u_1(\theta) = \int -\tan^2(\theta)\,d\theta$$
$$u_1(\theta) = \int \left(1 - \sec^2(\theta)\right)d\theta$$
$$u_1(\theta) = \theta - \tan(\theta)$$

$$u_2(\theta) = \int \frac{W_2}{W}\,d\theta$$
$$u_2(\theta) = \int \tan(\theta)\,d\theta$$
$$u_2(\theta) = \ln|\sec(\theta)|$$

Solving for $y_p(\theta)$.

$$y_p(x) = u_1 y_1 + u_2 y_2$$
$$y_p(x) = (\theta - \tan(\theta))(\cos(\theta)) + (\ln|\sec(\theta)|)(\sin(\theta))$$
$$y_p(x) = \theta\cos(\theta) - \sin(\theta) + \sin(\theta)\ln|\sec(\theta)|$$

Now combine and sum $y_c$ and $y_p$. Additionally, see how there is a repeated solution $\sin(\theta)$ that will get swallowed up by constant in $y_c$.

$$y_g(\theta) = y_c(\theta) + y_p(\theta)$$
$$y_g(\theta) = C_1 \cos(\theta) + C_2 \sin(\theta) + \theta \cos(\theta) \underbrace{- \sin(\theta)} + \sin(\theta) \ln|\sec(\theta)|$$
$$\Longrightarrow \boxed{y_g(\theta) = C_1 \cos(\theta) + C_2 \sin(\theta) + \theta \cos(\theta) + \sin(\theta) \ln|\sec(\theta)|}$$

## Problem 4.6.10

Given: $4y'' - y = e^{\frac{x}{2}} + 3$

Find: $y_g(x)$

**SOLUTION:** We simply use auxiliary equations for our complimentary equation and Cramer's rule to find our $u_1'$ and $u_2'$ to find our particular solution $y_p(x)$.

Solving for $y_c(x)$.

$$4y'' - y = e^{\frac{x}{2}} + 3$$
$$4m^2 - 1 = 0$$
$$m = \pm \frac{1}{2}$$
$$\Longrightarrow \boxed{y_c(x) = C_1 e^{\frac{x}{2}} + C_2 e^{-\frac{x}{2}}}$$

Solving for determinants $W$, $W_1$, $W_2$.

$$y_p(x) = u_1 y_1 + u_2 y_2$$
$$y_1(x) = e^{\frac{x}{2}}, \ y_2(x) = e^{-\frac{x}{2}}, \ f(x) = \frac{e^{\frac{x}{2}} + 3}{4}$$
$$W = \begin{vmatrix} e^{\frac{x}{2}} & e^{-\frac{x}{2}} \\ \frac{1}{2}e^{\frac{x}{2}} & -\frac{1}{2}e^{-\frac{x}{2}} \end{vmatrix}$$
$$W = e^{\frac{x}{2}} e^{-\frac{x}{2}} \begin{vmatrix} 1 & 1 \\ \frac{1}{2} & -\frac{1}{2} \end{vmatrix} = -1$$
$$W_1 = \begin{vmatrix} 0 & e^{-\frac{x}{2}} \\ \frac{e^{\frac{x}{2}}+3}{4} & -\frac{1}{2}e^{-\frac{x}{2}} \end{vmatrix}$$
$$W_1 = e^{-\frac{x}{2}} \begin{vmatrix} 0 & 1 \\ \frac{e^{\frac{x}{2}}+3}{4} & -\frac{1}{2} \end{vmatrix} = -\frac{1 + 3e^{-\frac{x}{2}}}{4}$$
$$W_2 = \begin{vmatrix} e^{\frac{x}{2}} & 0 \\ \frac{1}{2}e^{\frac{x}{2}} & \frac{e^{\frac{x}{2}}+3}{4} \end{vmatrix}$$
$$W_2 = e^{\frac{x}{2}} \begin{vmatrix} 1 & 0 \\ \frac{1}{2} & \frac{e^{\frac{x}{2}}+3}{4} \end{vmatrix}$$
$$W_2 = e^{\frac{1}{2}x} \left( \frac{1 + 3e^{\frac{x}{2}}}{4} \right)$$
$$W_2 = \frac{e^x + 3e^{\frac{x}{2}}}{4}$$

Solving for $u_1(x)$ and $u_2(x)$.

$$u_1(x) = \int \frac{W_1}{W}\,dx$$

$$u_1(x) = \int \frac{3e^{-\frac{x}{2}} + 1}{4}\,dx$$

$$u_1(x) = \frac{x - 6e^{-\frac{x}{2}}}{4}$$

$$u_2(x) = \int \frac{W_2}{W}\,dx$$

$$u_2(x) = \int \frac{-e^x - 3e^{\frac{x}{2}}}{4}\,dx$$

$$u_2(x) = \frac{-e^x - 6e^{\frac{x}{2}}}{4}$$

Solving for $y_p(x)$.

$$y_p(x) = u_1 y_1 + u_2 y_2$$

$$y_p(x) = \left(\frac{x - 6e^{-\frac{x}{2}}}{4}\right)\left(e^{\frac{x}{2}}\right) + \left(\frac{-e^x - 6e^{\frac{x}{2}}}{4}\right)\left(e^{-\frac{x}{2}}\right)$$

$$y_p(x) = \frac{xe^{\frac{x}{2}}}{4} - \frac{6}{4} - \frac{e^{\frac{x}{2}}}{4} - \frac{6}{4}$$

$$y_p(x) = \frac{xe^{\frac{x}{2}}}{4} - \frac{e^{\frac{x}{2}}}{4} - 3$$

Now combine and sum $y_c$ and $y_p$. Additionally, see how there is a repeated solution $-\frac{e^{\frac{x}{2}}}{4}$ that will get swallowed up by constant in $y_c$.

$$y_g(x) = y_c(x) + y_p(x)$$

$$y_g(x) = C_1 e^{\frac{x}{2}} + C_2 e^{-\frac{x}{2}} + \frac{xe^{\frac{x}{2}}}{4} - \frac{e^{\frac{x}{2}}}{4} - 3$$

$$\Longrightarrow \boxed{y_g(x) = C_1 e^{\frac{x}{2}} + C_2 e^{-\frac{x}{2}} + \frac{xe^{\frac{x}{2}}}{4} - 3}$$
